LOSSES IN PROFITS

Case Study #3: High Variability in Probiotics Concentration

Client: Probiotics Industrial Producer

Problem: High variability in product concentration at the end of standard batches

Context:

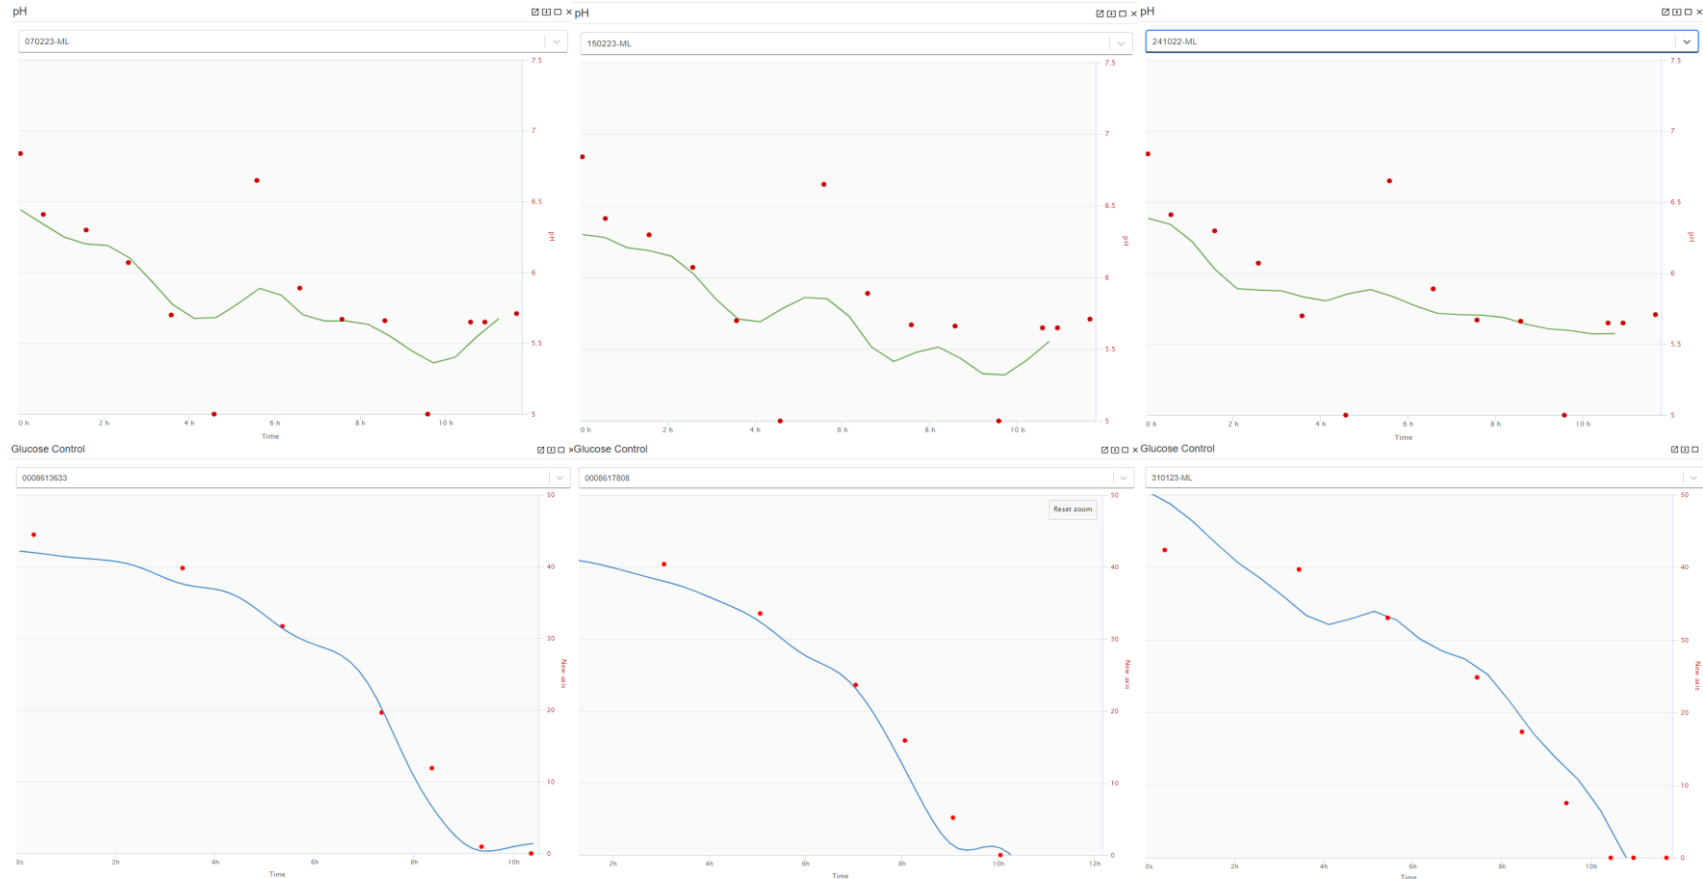

- At the end of a batch (EOB), the Client starts freeze drying the bacteria to produce the probiotics
- Not being able to measure glucose in real-time, they define years ago the “End of batch” to be:
 - EOB: **when pH profile switches from decreasing to increasing**
 - Hypothesis: resulting from glucose deprivation
- Client acquired the BioIntelligence Analytics Solution™ to automatize the end of batch, with hopes to reduce variability
- Our team began helping them to implement the automation and then, we figured out something...

Case Study #3: High Variability in Probiotics Concentration

1. To implement EOB automation, we had to **monitor pH live** using the BAS...

Case Study #3: High Variability in Probiotics Concentration

1. ... but it was not as good with Cell concentration:

Cell
concentration
(MV models)

Cell
concentration
(RNN models)

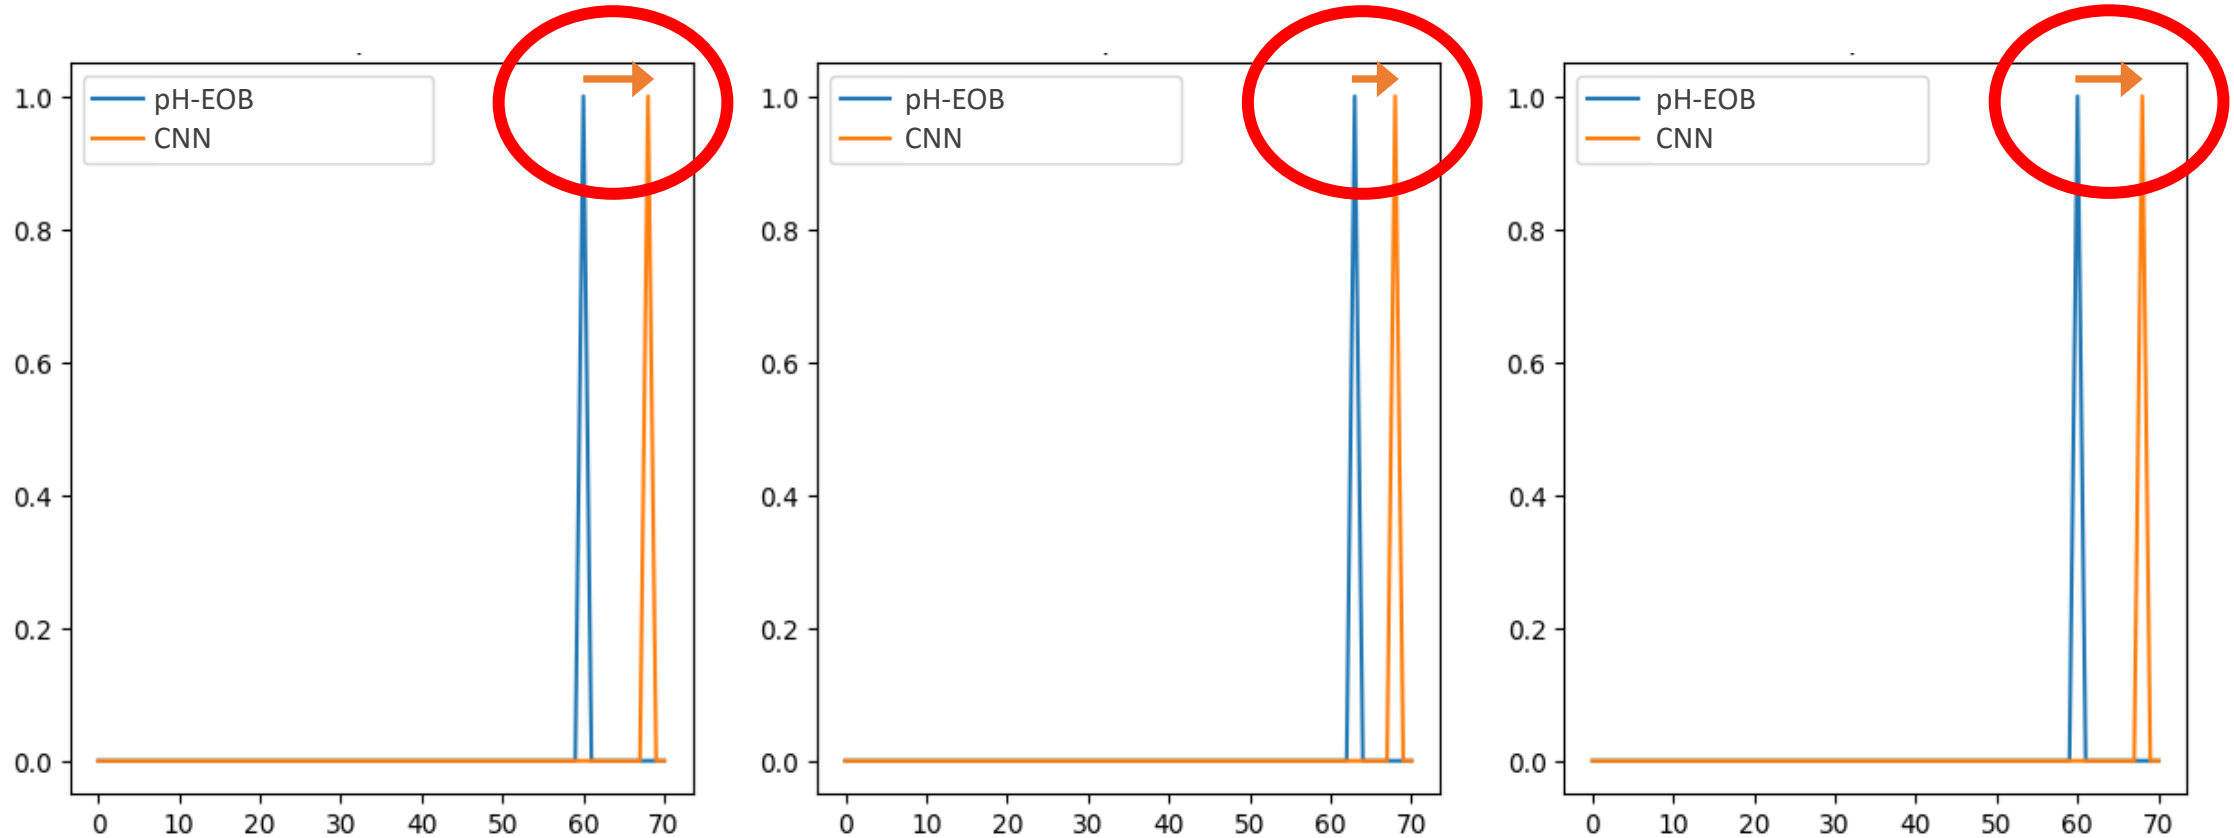

(RNN did not improve significantly the results)

Accuracy problems occur close to the EOB. Something happen then, before EOB?

Case Study #3: High Variability in Probiotics Concentration

2. Looked for alternative solutions:

- Can we use CNN to predict EOB (as defined from pH indication)?

EOB predicted by CNN is always 120-150 min late on pH-EOB. CNN on pH-EOB is NOT the solution.

Case Study #3: High Variability in Probiotics Concentration

pH-EOB Hypothesis:

- Current use of pH-EOB does not prevent **Variability**
- Modeled pH will NOT help, since it fits offline pH
- CNN on pH-EOB does NOT work and is always late
- Cell concentration modeling indicates **something happens hours before pH-EOB**.
 - Metabolism → Fluorescence ≠ Cell Concentration
 - **A metabolic shift happens before end of growth** (from Cell concentration)
 - Problems happens before pH-EOB
 - pH is not good indicator for “End of batch” and will not enable solving the variability problem

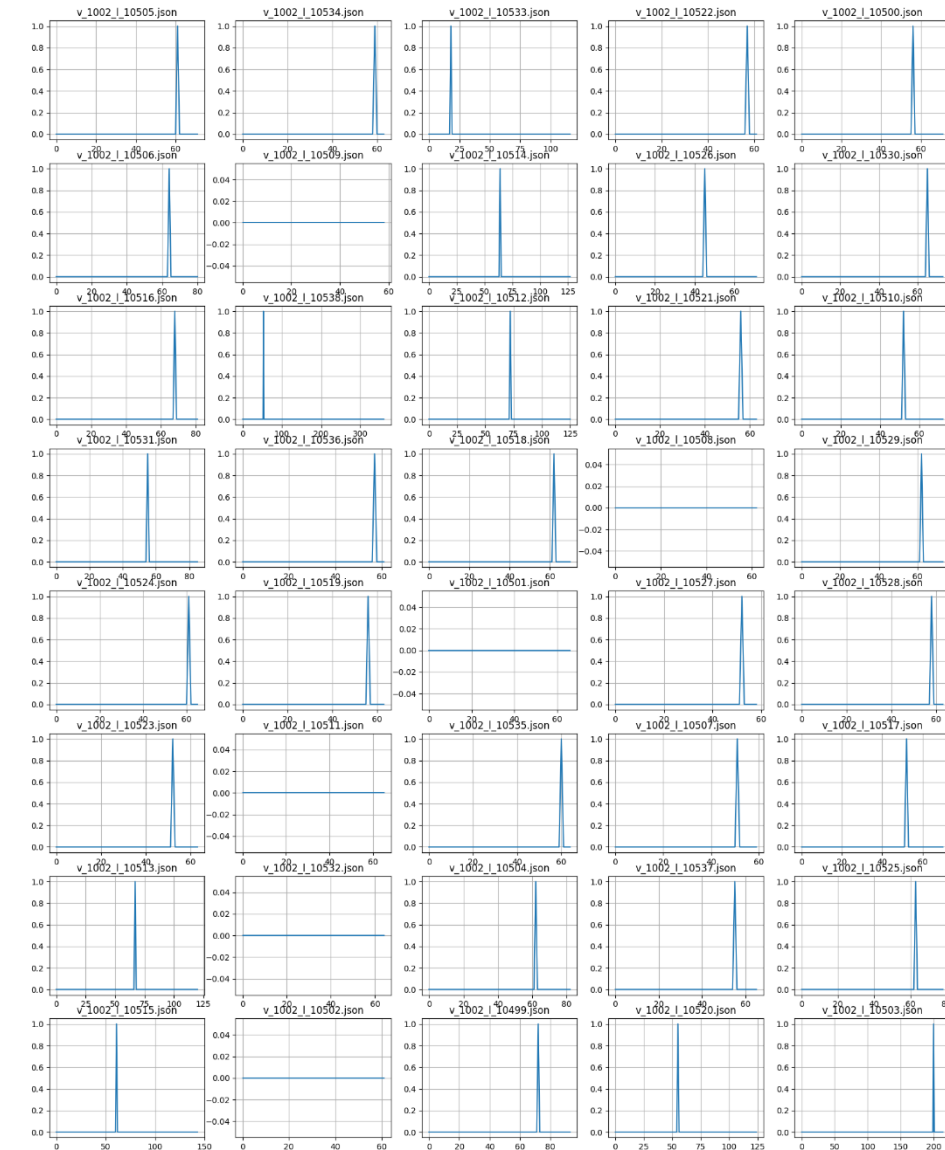

Case Study #3: High Variability in Probiotics Concentration

pH-EOB Hypothesis:

- Current use of pH-EOB does not prevent **Variability**
- Modeled pH will NOT help, since it fits offline pH
- CNN on pH-EOB does NOT work and is always late
- Cell concentration modeling indicates **something happens hours before pH-EOB**.
 - Metabolism → Fluorescence ≠ Cell Concentration
 - **A metabolic shift happens before end of growth** (from Cell concentration)
 - Problems happens before pH-EOB
 - pH is not good indicator for “End of batch” and will not enable solving the variability problem
- **Since we have been able to model Glucose, why not using Glucose as an indicator for EOB now on?**

Case Study #3: High Variability in Probiotics Concentration

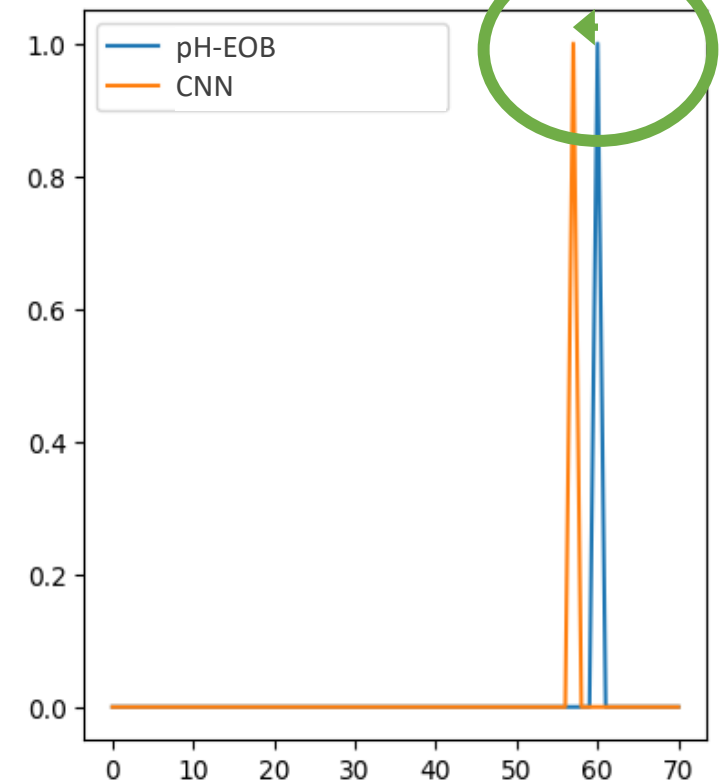

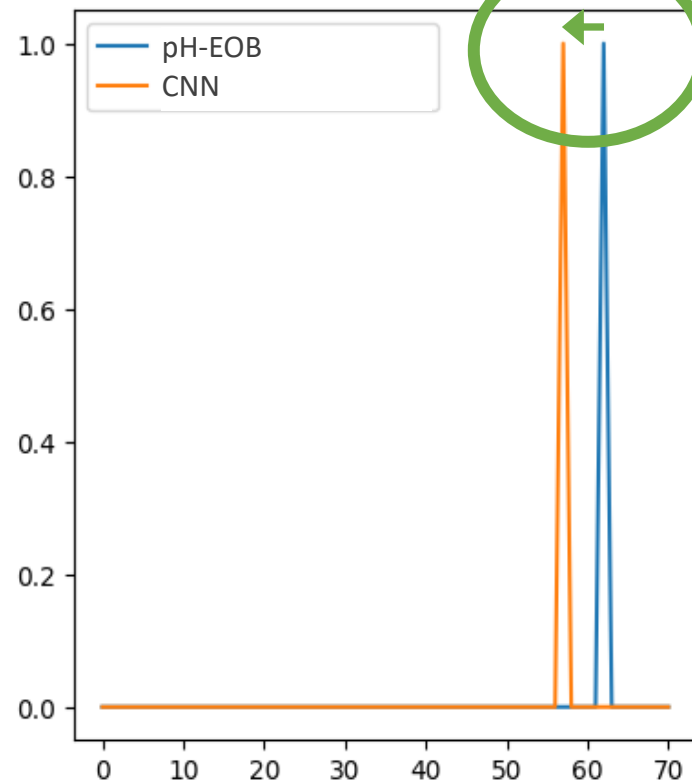

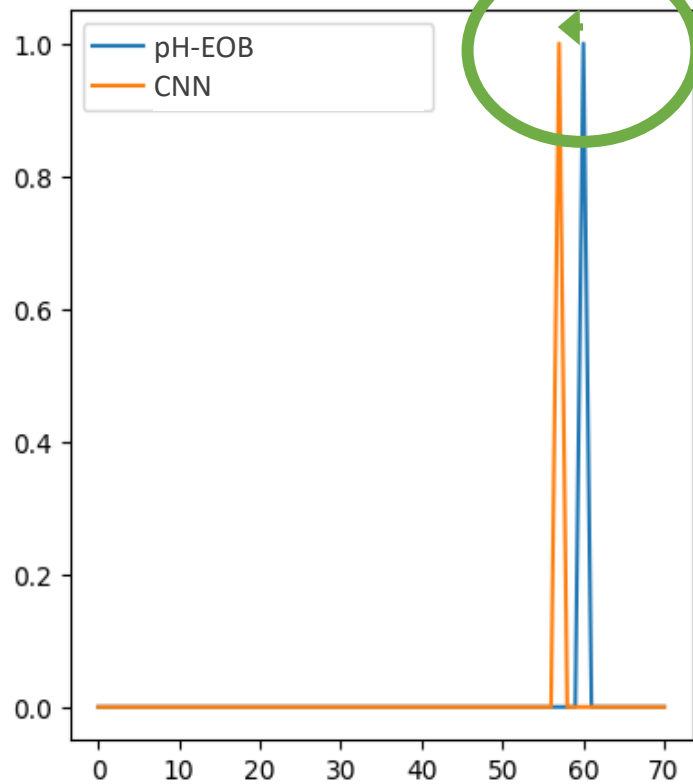

- Exploring the feasibility of a “Glucose-Deprivation-Indicator” (GDI):
 - First, apply glucose model on all fermentations available to identify GDI (i.e. the moment Glucose is completely consumed)

Case Study #3: High Variability in Probiotics Concentration

3. Exploring the feasibility of a “Glucose-Deprivation-Indicator” (GDI):

- First, apply glucose model on all fermentations available to identify GDI (i.e. the moment Glucose is completely consumed)
- Can we use CNN to predict GDI?

CNN is closer to GDI (than pH-EOB) and always 30-45 min earlier. CNN-GDI is a lead-predictor of the actual EOB.

Case Study #3: High Variability in Probiotics Concentration

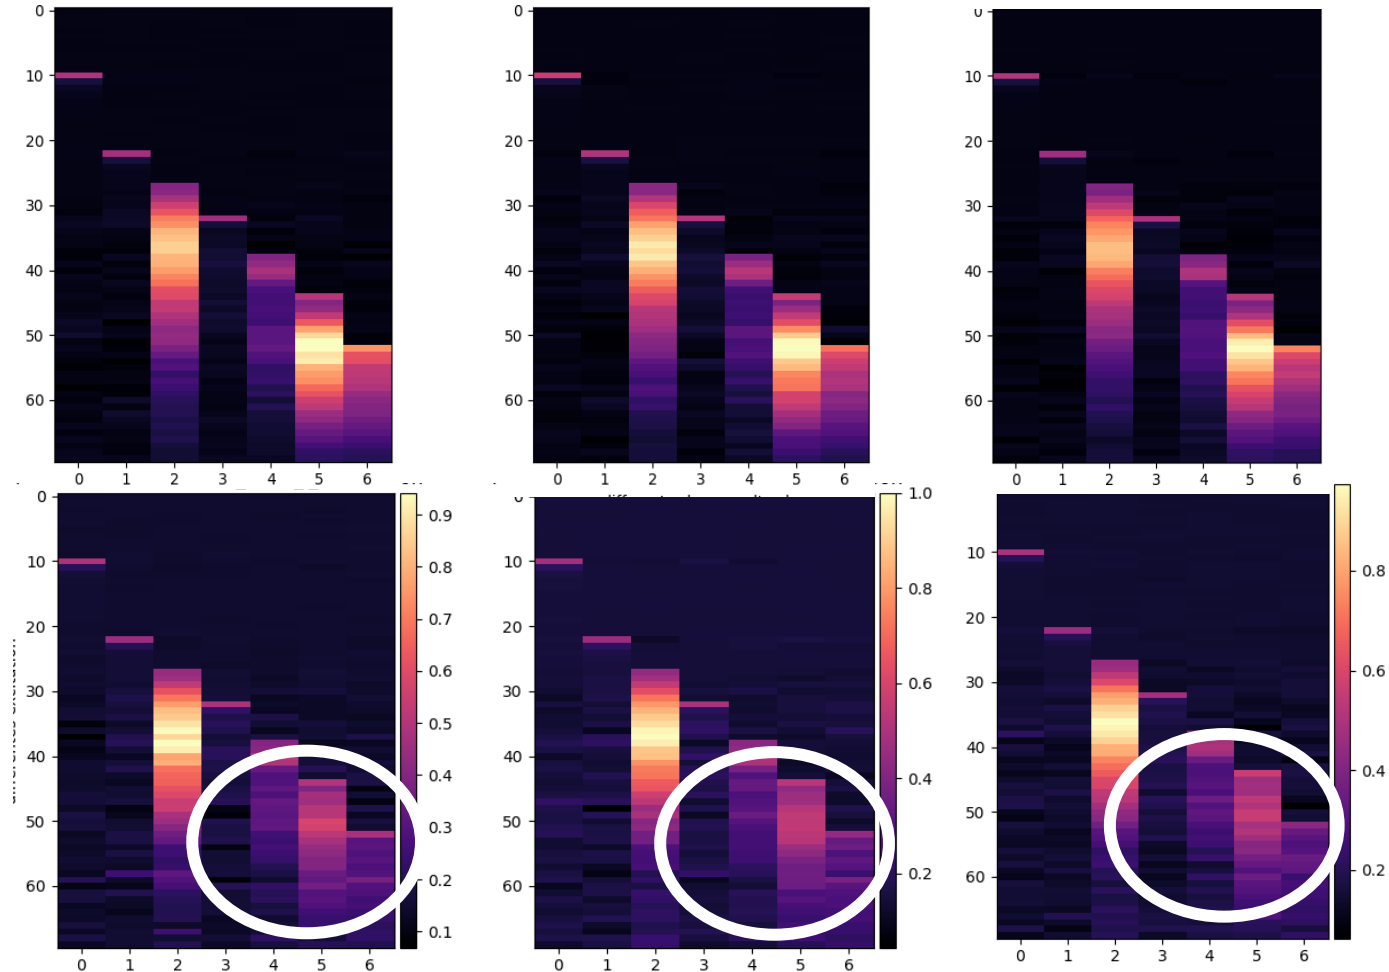

Glucose-Deprivation-Indicator Hypothesis:

- GDI is captured by CNN **30-45 minutes before** Glucose Deprivation
- Strong indication of GDI being an indicator of a metabolic shift leading to what should be the EOB
- **GDI is a very high-potential & actionable indicator to prevent Variability**
- Implementation is ongoing...

Case Study #3: High Variability in Probiotics Concentration

4. Bonus: Exploring Clustering as a Real-time indicator of Quality vs Problems

- Comparing 3D optical spectrum: Beginning vs End of batch

3D imprints at Start and at End are different. Does clustering help identify relevant models?

Case Study #3: High Variability in Probiotics Concentration

4. Bonus: Exploring Clustering as a Real-time indicator of Quality vs Problems

- Comparing 3D optical spectrum profiles at the End of batch

End of batch 3D imprints also contain slight differences.

Case Study #3: High Variability in Probiotics Concentration

4. Bonus: Exploring Clustering as a Real-time indicator of Quality vs Problems

- Using Clusters to:
 - a. Characterize the quality of fermentation right from the start
 - b. Get notification (Try to avoid?) when GBI is to be triggered

End of batch 3D imprints also contain slight differences.

Case Study #3: High Variability in Probiotics Concentration

Conclusion:

- **pH-EOB Hypothesis is wrong and of no help to prevent Variability**
- **CNN-GDI revealed to be a high-potential & actionable lead-predictor for the EOB to come**
- **Clustering already enabled the team to assess Initial fermentation quality & GDI triggering**
